The FT232H is a single channel USB 2.0 Hi-Speed (480Mb/s) to UART/FIFO IC. It has the capability of being configured in a variety of industry standard serial or parallel interfaces. The FT232H has the following advanced features:

- Single channel USB to serial / parallel ports with a variety of configurations.
- Entire USB protocol handled on the chip. No USB specific firmware programming required.
- USB 2.0 Hi-Speed (480Mbits/Second) and Full Speed (12Mbits/Second) compatible.
- Multi-Protocol Synchronous Serial Engine (MPSS) to simplify synchronous serial protocol (USB to JTAG, I2C, SPI (MASTER) or bit-bang) design.
- UART transfer data rate up to 12Mbaud. (RS232 Data Rate limited by external level shifter).
- USB to asynchronous 245 FIFO mode for transfer data rate up to 8 Mbyte/Sec.
- USB to synchronous 245 parallel FIFO mode for transfers up to 40 Mbytes/Sec.
- Supports a proprietary half duplex FT1248 interface with a configurable width, bi-directional data bus (1, 2, 4 or 8 bits wide).
- CPU-style FIFO interface mode simplifies CPU interface design.
- Fast serial interface option.
- FTDI’s royalty-free Virtual Com Port (VCP) and Direct (D2XX) drivers eliminate the requirement for USB driver development in most cases.
- Adjustable receive buffer timeout.
- Option for transmit and receive LED drive signals.
- Bit-bang Mode interface option with RD# and WR# strobes.
- Highly integrated design includes 5V to 3.3/+1.8V LDO regulator for VCORE, integrated POR function.
- Asynchronous serial UART interface option with full hardware handshaking and modern interface signals.
- Fully assisted hardware or X-On / X-Off software handshaking.
- UART Interface supports 7/8 bit data, 1/2 stop bits, and Odd/Even/Mark/Space/No Parity.
- Auto transmit enable control for RS485 serial applications using the TXDEN pin.
- Operational mode configuration and USB Description strings configurable in external EEPROM over the USB interface.
- Configurable I/O drives strength (4, 8, 12 or 16mA) and slew rate.
- Low operating and USB suspend current.
- Supports self-powered, bus powered and high-power bus powered USB configurations.
- UHCI/OHCI/EHCI host controller compatible.
- USB Bulk data transfer mode (512 byte packets in Hi-Speed mode).
- +1.8V (chip core) and +3.3V I/O interfacing (+5V Tolerant).
- Extended -40°C to 85°C industrial operating temperature range.
- Compact 48-pin Lead Free LQFP or QFN package.
- Configurable ACBUS I/O pins.
1 Typical Applications

- Single chip USB to UART (RS232, RS422 or RS485)
- USB to FIFO
- USB to FT1248
- USB to JTAG
- USB to SPI
- USB to I²C
- USB to Bit-Bang
- USB to Fast Serial Interface
- USB to CPU target interface (as memory)
- USB Instrumentation
- USB Industrial Control
- USB EPOS Control
- USB MP3 Player Interface
- USB FLASH Card Reader / Writers
- Set Top Box - USB interface
- USB Digital Camera Interface
- USB Bar Code Readers

1.1 Driver Support

The FT232H requires USB device drivers (listed below), available free from [http://www.ftdichip.com](http://www.ftdichip.com), to operate. The VCP version of the driver creates a Virtual COM Port allowing legacy serial port applications to operate over USB e.g. serial emulator application TTY. Another FTDI USB driver, the D2XX driver, can also be used with application software to directly access the FT232H through a DLL.

Royalty free VIRTUAL COM PORT (VCP) DRIVERS for...
- Windows 10 and Windows 10 64-bit
- Windows 8 and Windows 8 64-bit
- Windows 7 and Windows 7 64-bit
- Windows Vista and Vista 64-bit
- Windows XP and XP 64-bit
- Windows XP Embedded
- Windows CE 4.2, 5.0, 5.2 and 6.0
- Mac OS-X
- Linux (2.6.39 or later)

Royalty free D2XX Direct Drivers (USB Drivers + DLL S/W Interface)
- Windows 10 and Windows 10 64-bit
- Windows 8 and Windows 8 64-bit
- Windows 7 and Windows 7 64-bit
- Windows Vista and Vista 64-bit
- Windows XP and XP 64-bit
- Windows XP Embedded
- Windows CE 4.2, 5.0, 5.2 and 6.0
- Mac OS-X
- Linux (2.6.32 or later)
1.2 Part Numbers

</tr>
<tr>
<td>FT232HQ-xxxx</td>
<td>48 Pin QFN</td>
</tr>
</tbody>
</table>

**Note:** Packaging codes for xxxx is:
- Reel: Taped and Reel (LQFP = 1500 pieces per reel, QFN = 3000 pieces per reel)
- Tray: Tray packing, (LQFP = 250 pieces per tray, QFN = 260 pieces per tray)

Please refer to section 8 for all package mechanical parameters.

1.3 USB Compliant

The FT232H is fully compliant with the USB 2.0 specification and has been given the USB-IF Test-ID (TID) 40770005.

The timing of the rise/fall time of the USB signals is not only dependant on the USB signal drivers, it is also dependant system and is affected by factors such as PCB layout, external components and any transient protection present on the USB signals. For USB compliance these may require a slight adjustment. This timing can be modified through a programmable setting stored in the same external EEPROM that is used for the USB descriptors. Timing can also be changed by adding appropriate passive components to the USB signals.
2 FT232H Block Diagram

Figure 2.1 FT232H Block Diagram

A full description of each function is available in section 4.

3 Device Pin Out and Signal Descriptions

The 48-pin LQFP and 48-pin QFN have the same pin numbering for specific functions. This pin numbering is illustrated in the schematic symbol shown in Figure 3.1.

3.1 Schematic Symbol

![Schematic Symbol Diagram](image)

Figure 3.1 FT232H Schematic Symbol
3.2 FT232H Pin Descriptions

This section describes the operation of the FT232H pins. Both the LQFP and the QFN packages have the same function on each pin. The function of many pins is determined by the configuration of the FT232H. The following table details the function of each pin dependent on the configuration of the interface. Each of the functions is described in the following table (Note: The convention used throughout this document for active low signals is the signal name followed by #).

Pins marked * require an EEPROM for assignment to these functions. Default is Tristate, Pull-Up

Pins marked ** default to tri-stated inputs with an internal 75KΩ (approx.) pull up resistor to VCCIO.

Pin marked *** default to GPIO line with an internal 75KΩ pull down resistor to GND. Using the EEPROM this pin can be enabled USBVCC mode instead of GPIO mode.
### 3.3 Signal Description

The operation of the following FT232H pins are the same regardless of the configured mode:

<table>

Table 3.4 UART Interface and ACBUS Group (see note 1)
Notes:
When used in Input Mode, the input pins are pulled to VCCIO via internal 75kΩ (approx.) resistors. These pins can be programmed to gently pull low during USB suspend (PWREN# = “1”) by setting an option in the EEPROM.

3.4 ACBUS Signal Option

If the external EEPROM is fitted, the following options can be configured on the CBUS I/O pins using the software utility **FT_PROG** which can be downloaded from the **FTDI utilities** page. CBUS signal options are common to both package versions of the FT232H. The default configuration is described in section 7.

### Table 3.5 ACBUS Configuration Control

* Must be used with a 10kΩ resistor pull up.
**When in USB suspend mode the outputs clocks are also suspended.

### 3.5 Pin Configurations

The following section describes the function of the pins when the device is configured in different modes of operation.

#### 3.5.1 FT232H pins used in an UART interface

The FT232H can be configured as a UART interface. When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.6.

<table>

**Note:** UART is the device default mode.

### 3.5.2 FT232H Pins used in an FT245 Synchronous FIFO Interface

The FT232H can be configured as a FT245 synchronous FIFO interface. When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.7. To set this mode the external EEPROM must be set to 245 modes. A software command (FT_SetBitMode) is then sent by the application to the FTDI D2XX driver to tell the chip to enter 245 synchronous FIFO mode. In this mode, data is written or read on the rising edge of the CLKOUT. Refer to Figure 4.4 for timing details.

### 3.5.3 FT232H Pins used in an FT245 Style Synchronous FIFO Interface

The FT232H can be configured as a FT245 style asynchronous FIFO interface. When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.8. To enter this mode the external EEPROM must be set to 245 asynchronous FIFO mode. In this mode, data is written or read on the falling edge of the RD# or WR# signals.

3.5.4 FT232H Configured as a Synchronous or Asynchronous Bit-Bang Interface

Bit-bang mode is an FTDI FT232H device mode that changes the 8 IO lines into an 8 bit bi-directional data bus. This mode is enabled by sending a software command (FT_SetBitMode) to the FTDI driver. When configured in any bit-bang mode, the pins used and the descriptions of the signals are shown in Table 3.9.

For functional description of this mode, please refer to section 4.6.

3.5.5 FT232H Pins used in an MPSSE

The FT232H has a Multi-Protocol Synchronous Serial Engine (MPSSE). This mode is enabled by sending a software command (FT_SetBitMode) to the FTDI D2xx driver. The MPSSE can be configured to a number of industry standard serial interface protocols such as JTAG, I2C or SPI (MASTER), or it can be used to implement a proprietary bus protocol. For example, it is possible to connect FT232H’s to an SRAM configurable FPGA such as supplied by Altera or Xilinx. The FPGA device would normally not be configured (i.e. have no defined function) at power-up. Application software on the PC could use the MPSSE (and D2XX driver) to download configuration data to the FPGA over USB. This data would define the hardware function on power up. The MPSSE can be used to control a number of GPIO pins. When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.10.

Table 3.10 MPSSE Configured Pin Descriptions

For functional description of this mode, please refer to section 4.8.

3.5.6 FT232H Pins used as a Fast Serial Interface

The FT232H can be configured for use with high-speed bi-directional isolated serial data. A proprietary FTDI protocol designed to allow galvanic isolated devices to communicate synchronously with the FT232H using just 4 signal wires (over two dual opto-isolators), and two power lines. The peripheral circuitry controls the data transfer rate in both directions, whilst maintaining full data integrity. 12 Mbps (USB full speed) data rates can be achieved when using the proper high speed opto-isolators (see App Note AN-131).

When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.11.
16 | FSCTS | OUTPUT | Fast serial Clear To Send signal output. Driven low to indicate that the chip is ready to send data
---|---|---|---
28 | SIWU# | INPUT | The Send Immediate / WakeUp signal combines two functions on a single pin. If USB is in suspend mode (PWREN# = 1) and remote wakeup is enabled in the EEPROM, strobing this pin low will cause the device to request a resume on the USB Bus. Normally, this can be used to wake up the Host PC. During normal operation (PWREN# = 0), if this pin is strobed low any data in the device RX buffer will be sent out over USB on the next Bulk-IN request from the drivers regardless of the pending packet size. This can be used to optimize USB transfer speed for some applications. Tie this pin to VCCIO if not used.

For a functional description of this mode, please refer to section 4.9.

3.5.7 FT232H Pins Configured as a CPU-style FIFO Interface

The FT232H can be configured in a CPU-style FIFO interface mode which allows a CPU to interface to USB via the FT232H. This mode is enabled in the external EEPROM.

When configured in this mode, the pins used and the descriptions of the signals are shown in Table 3.12.

Table 3.13 FT1248 Configured Pin Descriptions

For functional description of this mode, please refer to section 4.
4 Function Description

The FT232H USB 2.0 Hi-Speed (480Mb/s) to UART/FIFO is an FTDI’s 6th generation of ICs. It can be configured in a variety of industry standard serial or parallel interfaces, such as UART, FIFO, JTAG, SPI (MASTER) or I²C modes. In addition to these, the FT232H introduces the FT1248 interface and supports a CPU-Style FIFO mode, bit-bang and a fast serial interface mode.

4.1 Key Features

USB Hi-Speed to UART/FIFO Interface. The FT232H provides USB 2.0 Hi-Speed (480Mbits/s) to flexible and configurable UART/FIFO Interfaces.

Functional Integration. The FT232H integrates a USB protocol engine which controls the physical Universal Transceiver Macrocell Interface (UTMI) and handles all aspects of the USB 2.0 Hi-Speed interface. The FT232H includes an integrated +1.8V/3.3V Low Drop-Out (LDO) regulator. It also includes 1Kbytes Tx and Rx data buffers. The FT232H integrates the entire USB protocol on a chip with no firmware required.

MPSSE. Multi-Protocol Synchronous Serial Engines (MPSSE), capable of speeds up to 30 Mbits/s, provides flexible synchronous interface configurations.

FT1248 interface. The FT232H supports a new proprietary half-duplex FT1248 interface with a variable bi-directional data bus interface that can be configured as 1, 2, 4, or 8-bits wide and this enables the flexibility to expand the size of the data bus to 8 pins. For details regarding 2-bit, 4-bit and 8-bit modes, please refer to application note AN_167_FT1248_Serial_Parallel Interface Basics available from the FTDI website.

Data Transfer rate. The FT232H supports a data transfer rate up to 12 Mbaud when configured as an RS232/RS422/RS485 UART interface up to 40 Mbytes/second over a synchronous 245 parallel FIFO interface or up to 8 Mbyte/Sec over an asynchronous 245 FIFO interface. Please note the FT232H does not support the baud rates of 7 Mbaud 9 Mbaud, 10 Mbaud and 11 Mbaud.

Latency Timer. A feature of the driver used as a timeout to transmit short packets of data back to the PC. The default is 16ms, but it can be altered between 0ms and 255ms.

Bus (ACBUS) functionality, signal inversion and drive strength selection. There are 11 configurable ACBUS I/O pins. These configurable options are:

1. TXDEN – transmit enable for RS485 designs.
2. PWREN# - Power control for high power, bus powered designs.
3. TXLED# - for pulsing an LED upon transmission of data.
4. RXLED# - for pulsing an LED upon receiving data.
5. TX&RXLED# - which will pulse an LED upon transmission OR reception of data.
6. SLEEP# - indicates that the device going into USB suspend mode.
7. CLK30 / CLK15 / CLK7.5 – 30MHz, 15MHz and 7.5MHz clock output signal options.
8. Trist-PU – Input pulled up, not used
9. DRIVE 1 – Output driving high
10. DRIVE 0 – Output driving low
11. I/O mode – ACBUS Bit Bang

The ACBUS pins can also be individually configured as GPIO pins, similar to asynchronous bit bang mode. It is possible to use this mode while the UART interface is being used, thus providing up to 4 general purpose I/O pins which are available during normal operation.

The ACBUS lines can be configured with any one of these input/output options by setting bits in the external EEPROM see section 0.
4.2 Functional Block Descriptions

Multi-Purpose UART/FIFO Controllers. The FT232H has one independent UART/FIFO Controller. This controls the UART data, 245 FIFO data, Fast Serial (opto isolation) or Bit-Bang mode which can be selected by SETUP (FT_SetBitMode) command. Each Multi-Purpose UART/FIFO Controller also contains an MPSSE (Multi-Protocol Synchronous Serial Engine). Using this MPSSE, the Multi-Purpose UART/FIFO Controller can be configured under software command, to have one of the MPSSE (SPI (MASTER), I2C, and JTAG).

USB Protocol Engine and FIFO control. The USB Protocol Engine controls and manages the interface between the UTMI PHY and the FIFOs of the chip. It also handles power management and the USB protocol specification.

Port FIFO TX Buffer (1Kbytes). Data from the Host PC is stored in these buffers to be used by the Multi-purpose UART/FIFO controllers. This is controlled by the USB Protocol Engine and FIFO control block.

Port FIFO RX Buffer (1Kbytes). Data from the Multi-purpose UART/FIFO controllers is stored in these blocks to be sent back to the Host PC when requested. This is controlled by the USB Protocol Engine and FIFO control block.

RESET Generator – The integrated Reset Generator Cell provides a reliable power-on reset to the device internal circuitry at power up. The RESET# input pin allows an external device to reset the FT232H. RESET# should be tied to VCCIO (+3.3V) if not being used.

Baud Rate Generators – The Baud Rate Generators provides an x16 or an x10 clock input to the UART’s from a 120MHz reference clock and consists of a 14 bit pre-scaler and 4 register bits which provide fine tuning of the baud rate (used to divide by a number plus a fraction). This determines the Baud Rate of the UART which is programmable from 183 baud to 12 Mbaud. See FTDI application note AN_120 on the FTDI website for more details.

EEPROM Interface. If the external EEPROM is fitted, the FT232H can be configured as an asynchronous serial UART (default mode), parallel FIFO (245) mode, FT1248, fast serial (opto isolation) or CPU-Style FIFO. The EEPROM should be a 16 bit wide configuration such as a 93LC56B or equivalent capable of a 1Mbit/s clock rate at VCCIO = +2.97V to 3.63V. The EEPROM is programmable in-circuit over USB using a utility program called FT_Prog available from FTDI web site. Please note that the 93LC46B is not compatible with the FT232H device.

+1.8/3.3V LDO Regulator. The +3.3/+1.8V LDO regulator generates +1.8 volts for the core and the USB transceiver cell and +3.3V for the IO and the internal PLL and USB PHY power supply.

UTMI PHY. The Universal Transceiver Macrocell Interface (UTMI) physical interface cell. This block handles the Full speed / Hi-Speed SERDES (serialise – deserialise) function for the USB TX/RX data. It also provides the clocks for the rest of the chip. A 12 MHz crystal must be connected to the OSCI pin or 12 MHz Oscillator must be connected to the OSCI, and the OSCO pin is left unconnected. A 12K Ohm resistor should be connected between REF and GND on the PCB.

The UTMI PHY functions include:

- Supports 480 Mbit/s "Hi-Speed" (HS)/ 12 Mbit/s "Full Speed" (FS).
- SYNC/EOP generation and checking
- Data and clock recovery from serial stream on the USB.
- Bit-stuffing/unstuffing; bit stuff error detection.
- Manages USB Resume, Wake Up and Suspend functions.
- Single parallel data clock output with on-chip PLL to generate higher speed serial data clocks.
4.3 FT232 UART Interface Mode Description

The FT232H can be configured as a UART with external line drivers, similar to operation with the FTDI FT232R devices. The following examples illustrate how to configure the FT232H with an RS232, RS422 or RS485 interface.

4.3.1 RS232 Configuration

Figure 4.1 illustrates how the FT232H can be configured with an RS232 UART interface.
### 4.3.2 RS422 Configuration

Figure 4.2 illustrates how the FT232H can be configured as a RS422 interface.

![Figure 4.2 Dual RS422 Configuration](image)

In this case the FT232H is configured as UART operating at TTL levels and a level converter device (full duplex RS485 transceiver) is used to convert the TTL level signals from the FT232H to RS422 levels. The PWREN# signal is used to power down the level shifters such that they operate in a low quiescent current when the USB interface is in suspend mode.
4.3.3 RS485 Configuration

Figure 4.3 illustrates how the FT232H can be configured as a RS485 interface.

In this case the FT232H is configured as a UART operating at TTL levels and a level converter device (half duplex RS485 transceiver) is used to convert the TTL level signals from the FT232H to RS485 levels. With RS485, the transmitter is only enabled when a character is being transmitted from the UART. The TXDEN pin on the FT232H is provided for exactly that purpose, and so the transmitter enables are wired to the TXDEN. RS485 is a multi-drop network – i.e. many devices can communicate with each other over a single two wire cable connection. The RS485 cable requires to be terminated at each end of the cable. Links are provided to allow the cable to be terminated if the device is physically positioned at either end of the cable.
4.4 FT245 Synchronous FIFO Interface Mode Description

When FT232H is configured in an FT245 Synchronous FIFO interface mode the IO timing of the signals used are shown in Figure 4.4 which shows details for read and write accesses. The timings are shown in Figure 4.4. Note that only a read or a write cycle can be performed at any one time. Data is read or written on the rising edge of the CLKOUT clock.

This mode uses a synchronous interface to get high data transfer speeds. The chip drives a 60 MHz CLKOUT clock for the external system to use.

Note that Asynchronous FIFO mode must be selected in the EEPROM before selecting the Synchronous FIFO mode in software.

#### 4.4.1 FT245 Synchronous FIFO Read Operation

A read operation is started when the chip drives RXF# low. The external system can then drive OE# low to turn the data bus drivers around before acknowledging the data with the RD# signal going low. The first data byte is on the bus after OE# is low. The external system can burst the data out of the chip by keeping RD# low or it can insert wait states in the RD# signal. If there is more data to be read it will change on the clock following RD# sampled low. Once all the data has been consumed, the chip will drive RXF# high. Any data that appears on the data bus, after RXF# is high, is invalid and should be ignored.

#### 4.4.2 FT245 Synchronous FIFO Write Operation

A write operation can be started when TXE# is low. WR# is brought low when the data is valid. A burst operation can be done on every clock providing TXE# is still low. The external system must monitor TXE# and its own WR# to check that data has been accepted. Both TXE# and WR# must be low for data to be accepted.
4.5 FT245 Style Asynchronous FIFO Interface Mode Description

The FT232H can be configured as an asynchronous FIFO interface. This mode is similar to the synchronous FIFO interface with the exception that the data is written to or read from the FIFO on the falling edge of the WR# or RD# signals.

This mode does not provide a CLKOUT signal and it does not expect an OE# input signal. The following diagrams illustrate the asynchronous FIFO mode timing.

Table 4.2 Asynchronous FIFO Timings (based on standard drive level outputs)
4.6 FT1248 Interface Mode Description

The FT232H supports a half-duplex FT1248 Interface that provides a flexible data communication and high performance interface between the FT232H as a FT1248 slave and an external FT1248 master. The FT1248 protocol is a dynamic bi-directional data bus interface that can be configured as 1, 2, 4, or 8-bits wide.

In the FT1248 there are 3 distinct phases:

While SS_n is inactive, the FT1248 reflects the status of the write buffer and read buffers on the MIOSIO[0] and MISO wires respectively. Additionally, the FT1248 slave block supports multiple slave devices where a master can communicate with multiple FT1248 slave devices. When the slave is sharing buses with other FT1248 slave devices, the write and read buffer status cannot be reflected on the MIOSIO[0] and MISO wires during SS_n inactivity as this would cause bus contention. Therefore, it is possible for the user to select whether they wish to have the buffer status switched on or off during inactivity. When SS_n is active a command/bus size phase occurs first. Following the command phase is the data phase, for each data byte transferred the FT1248 slave drives an ACK/NAK status onto the MISO wire. The master can send multiple data bytes so long as SS_n is active, if an unsuccessful data transfer occurs, i.e. a NAK happens on the MISO wire then the master should immediately abort the transfer by de-asserting SS_n.

Section 4.6.2 illustrates the FT1248 write and read protocol operating in 1-bit mode. For details regarding 2-bit, 4-bit and 8-bit modes, please refer to application note AN_167_FT1248 Parallel Serial Interface Basics available at [http://www.ftdichip.com](http://www.ftdichip.com).
4.6.1  Bus Width Protocol Decode

In order for the FT1248 master to determine the bus width within the command phase the bus width is encoded along with the actual commands on the first active clock edge when SS\_n is active and has a data width of 8-bits.

If any of the MIOSIO [7:4] signals are low then the data transfer width equals 8-bits.

If any of the MIOSIO [3:2] signals are low then the data transfer width equals 4-bits.

If MIOSIO [1] signal is low then the data transfer width equals 2-bits.

Else the bus width is defaulted to 1-bit.

Please note that if both of the MIOSIO bit signals are low then the data transfer width is equal to the width of high priority MIOSIO bit signal. For example if both of the MIOSIO [7:3] signals are low then the data transfer width equals 8-bits or if both of the MIOSIO [3:1] signals are low then the data transfer width equals 4-bits.

In order to successfully decode the bus width, all MIOSIO signals must have pull up resistors. By default, all MIOSIO signals shall be seen by the FT232H in FT1248 mode as logic ‘1’. This means that when a FT1248 master does not wish to use certain MIOSIO signals the slave (FT232H) is still capable of determining the requested bus width since any unused MIOSIO signals shall be pull up in the slave.

The remaining bits used during the command phase are used to contain the command itself which means that it is possible to define up to 16 unique commands.

Figure 4.9 FT1248 Command Structure

For more details about FT1248 Interface, please refer to application note AN_167_FT1248 Parallel Serial Interface Basics available at [http://www.ftdichip.com](http://www.ftdichip.com).
4.6.2 FT1248: 1-bit interface

The FT1248 Interface transfers data over different bus widths (1-bit, 2-bit, 4-bit and 8-bit). Figure 4.21 and Figure 4.22 illustrate the waveform detailing the FT1248 write and read protocol operating in 1-bit mode with flow control. Please refer to the application notes AN_167_FT1248 Parallel Serial Interface Basics available at http://www.ftdichip.com for more details regarding 1-bit without flow control, 2-bit, 4-bit and 8-bit modes.

Figure 4.10 FT1248 1-bit Mode Protocol (WRITE)

Figure 4.11 FT1248 1-bit Mode Protocol (READ)
When SS_n is inactive the write buffer and read buffer status is reflected on the MIOSIO[0] and MISO signals respectively. When the master wishes to initiate a data transfer, SS_n becomes active. As soon as SS_n becomes active the SPI slave immediately stops driving the MIOSIO[0] signal and SPI master is not allowed to begin driving the MIOSIO[0] signal until the first clock edge, this ensures that bus contention is avoided.

On the first clock edge the command is shifted out for 7 clocks, on the 8th clock cycle a bus turnaround is required. The bus turnaround is required as the slave may be required to drive the MIOSIO[0] bus with read data. The data phase occurs in response to the command and so long as SS_n remains active. The data phase in 1-bit mode requires 8 clock cycles where the MIOSIO[0] signal transfers the requested write or read data. The MISO signal indicates to the master the success of the transfer with an ACK or NAK.

The status is reflected through the whole of the data phase and is valid from the first clock edge. If the master is writing data to the slave, then on the last clock edge before it de-asserts SS_n must tristate the MIOSIO[0] signal to enable the bus to be "turned" around as when SS_n becomes inactive the FT1248 slave shall begin to drive the write buffer status onto the MIOSIO[0] signal. When the SPI slave is driving the MIOSIO[0] (the master is reading data) no bus turnaround is required as when SS_n becomes inactive it is required to drive the write buffer status to the FT1248 master.

4.7 Synchronous and Asynchronous Bit-Bang Interface Mode

The FT232H can be configured as a bit-bang interface. There are two types of bit-bang modes: synchronous and asynchronous.

See application note AN2232-02 Bit Mode Functions for the FT232 for more details and examples of using both Synchronous and Asynchronous bit-bang modes.

4.7.1 Asynchronous Bit-Bang Mode

Asynchronous Bit-Bang mode is the same as BM-style Bit-Bang mode, except that the internal RD# and WR# strobes (RDSTB# and WRSTB#) are now brought out of the device to allow external logic to be clocked by accesses to the bit-bang IO bus.

Any data written to the device in the normal manner will be self-clocked onto the data pins (those which have been configured as outputs). Each pin can be independently set as an input or an output. The rate that the data is clocked out at is controlled by the baud rate generator.

New data must be written, and the baud rate clock should tick to change the data. If no new data is written to the chip, the pins configured for output will hold the last value written.

Asynchronous Bit-Bang mode is enabled using the FT_SetBitMode D2xx driver command with a hex value of 0x01.

4.7.2 Synchronous Bit-Bang Mode

The synchronous Bit-Bang mode will only update the output parallel port pins whenever data is sent from the USB interface to the parallel interface. When this is done, the WRSTB# will activate to indicate that the data has been read from the USB Rx FIFO buffer and written out on the pins. Data can only be received from the parallel pins (to the USB Tx FIFO interface) after the parallel interface has been written to.

With Synchronous Bit-Bang mode data will only be sent out by the FT232H if there is space in the FT232H USB TXFIFO for data to be read from the parallel interface pins. This Synchronous Bit-Bang mode will read the data bus parallel I/O pins first, before it transmits data from the USB RxFIFO. It is therefore 1 byte behind the output, and so to read the inputs for the byte that you have just sent, another byte must be sent.

For example:

Figure 1. Pins start at 0xFF
Send 0x55, 0xAA
Pins go to 0x55 and then to 0xAA
Data read = 0xFF, 0x55
(2) Pins start at 0xFF
Send 0x55, 0xAA, 0xAA
(repeat the last byte sent)
Pins go to 0x55 and then to 0xAA
Data read = 0xFF, 0x55, 0xAA

Synchronous Bit-Bang Mode differs from Asynchronous Bit-Bang mode in that the device parallel output
is only read when the parallel output is written to by the USB interface. This makes it easier for the
controlling program to measure the response to a USB output stimulus as the data returned to the USB
interface is synchronous to the output data.

Synchronous Bit-Bang mode is enabled using Set Bit Bang Mode driver command with a hex value of
0x04.

An example of the synchronous bit-bang mode timing is shown in Figure 4.12

![Figure 4.12 Synchronous Bit-Bang Mode Timing Interface Example](image)

WRSTB# = this output indicates when new data has been written to the I/O pins from the Host PC (via
the USB interface).

<table>
<thead>

</tr>
<tr>
<td>t6</td>
<td>WRSTB# goes inactive</td>
</tr>
</tbody>
</table>

**Table 4.3 Synchronous Bit-Bang Mode Timing Interface Example Timings**

The WRSTB# goes active in t5. The WRSTB# goes active when data is read from the USB RXFIFO (i.e.
sent from the PC). The RDSTB# goes inactive when data is sampled from the pins and written to the USB TXFIFO (i.e. sent to the PC). The SETUP command to the FT232H is used to setup the bit-mode. This command also contains a byte wide data mask to set the direction of each bit. The direction on each pin doesn’t change unless a new SETUP command is used to modify the direction.

The WRSTB# and RDSTB# strobes are only a guide to what may be happening depending on the
direction of the bus. For example if all pins are configured as inputs, it is still necessary to write to these pins in order to get the FT232H to read those pins even though the data written will never appear on the pins.

Signals and data-flow are illustrated in Figure 4.13
4.8 MPSSE Interface Mode Description

MPSSE Mode is designed to allow the FT232H to interface efficiently with synchronous serial protocols such as JTAG, I²C and SPI (MASTER) Bus. It can also be used to program SRAM based FPGA’s over USB. The MPSSE interface is designed to be flexible so that it can be configured to allow any synchronous serial protocol (industry standard or proprietary) to be implemented using the FT232H.

MPSSE is fully configurable, and is programmed by sending commands down the data stream. These can be sent individually or more efficiently in packets. MPSSE is capable of a maximum sustained data rate of 30 Mbits/s.

When the FT232H is configured in MPSSE mode, the IO timing and signals used are shown in Figure 4.14 and Table 4.4. These show timings for CLKOUT=30MHz. CLKOUT can be divided internally to provide a slower clock.
4.8.1 MPSSE Adaptive Clocking

The Adaptive Clock mode correlates the CLK signal with a return clock RTCK. This is a technique used by ARM® processors.

The FT232H will assert the TCK line and wait for the RTCK to be returned from the target device to GPIOL3 line before changing the TDO (data out line).

MPSSE mode is enabled using the FT_SetBitMode D2xx driver command with a hex value of 0x02. A hex value of 0x00 will reset the device. See application note AN135 – MPSSE Basics for more details and examples.

The MPSSE command set is fully described in application note AN108 – Command Processor For MPSSE and MCU Host Bus Emulation Modes.
Adaptive clocking is not enabled by default.
For further details on MPSSE adaptive clocking please refer to AN_108 Command Processor For MPSSE and MCU Host Bus Emulation Modes.
4.9 Fast Serial Interface Mode Description

Fast Serial Interface Mode provides a method of communicating with an external device over USB using 4 wires that can have opto-isolators in their path, thus providing galvanic isolation between systems. Fast serial mode is enabled by setting the appropriate bits in the external EEPROM. The fast serial mode can be held in reset by setting a bit value of 0x10 using the FT_SetBitMode D2XX driver command. While this bit is set the device is held reset – data can be sent to the device, but it will not be sent out by the device until the device is enabled again. This is done by sending a bit value of 0x00 using the Set Bit Mode command.

When the FT232H is configured in Fast Serial Interface mode the IO timing of the signals used are shown in Figure 4.17 and the timings are shown in Table 4.5 Fast Serial Interface Signal Timings.

</tr>
</tbody>
</table>

Table 4.5 Fast Serial Interface Signal Timings
4.9.1 Outgoing Fast Serial Data

To send fast serial data out of the FT232H, the external device must drive the FSCLK clock. If the FT232H has data ready to send, it will drive FSDO output low to indicate the start bit. It will not do this if it is currently receiving data from the external device. This is illustrated in Figure 4.18.

![Figure 4.18 Fast Serial Interface Output Data](image)

**Notes:**

1. The first bit output (Start bit) is always 0.
2. FSDO is always sent LSB first.
3. The last serial bit output is the source bit (SRCE) is always 0.
4. If the target device is unable to accept the data when it detects the START bit, it should stop the FSCLK until it can accept the data.

4.9.2 Incoming Fast Serial Data

An external device is allowed to send data into the FT232H if FSCTS is high. On receipt of a zero START bit on FSDI, the FT232H will drop FSCTS on the next positive clock edge. The data from bits 0 to 7 are then clocked in (LSB first). The last bit (DEST) determines where the data will be written to. This bit is always 0 with the FT232H. This is illustrated in Figure 4.19.

![Figure 4.19 Fast Serial Interface Input Data](image)

**Notes:**

1. The first bit input (Start bit) is always 0.
2. FSDI is always received LSB first.
3. The last received serial bit is the destination bit (DEST) is always 0.
4. The target device should ensure that FSCTS is high before it sends data. FSCTS goes low after data bit 0 (D0) and stays low until the chip can accept more data.
4.9.3 Fast Serial Data Interface Example

Figure 4.20 shows an example of two Agilent HCPL-2430 (see the semiconductor section at www.avagotech.com) Hi-Speed opto-couplers used to optically isolate an external device which interfaced to USB using the FT232H. In this example VCCSV is the USB VBUS supply and VCCE is the supply to the external device.

Care must be taken with the voltage used to power the photo-LED. It must be the same voltage as that which the FT232H I/Os are driving to, or the LED’s may be permanently on. Limiting resistors should be fitted in the lines that drive the diodes. The outputs of the opto-couplers are open-collector and require a pull-up resistor.

4.10 CPU-style FIFO Interface Mode Description

CPU-style FIFO interface mode is designed to allow a CPU to interface to USB via the FT232H. This mode is enabled in the external EEPROM. The interface is achieved using a chip select bit (CS#) and address bit (A0). When the FT232H is in CPU-style Interface mode, the IO signal lines are configured as given in Table 4.6. This mode uses a combination of CS# and A0 to determine the operation to be carried out. The following Truth-Table 4.7 gives the decode values for particular operations.

Table 4.8 CPU-Style FIFO Interface Operation Signal Timing
An example of the CPU-style FIFO interface connection is shown in Figure 4.22.

### 4.11 RS232 UART Mode LDE Interface Description

When configured in UART mode the FT232H has two IO pins dedicated to controlling LED status indicators, one for transmitted data the other for received data. When data is being transmitted or received the respective pins drive from tristate to low in order to provide indication on the LED’s of data transfer. A digital one-shot timer is used so that even a small percentage of data transfer is visible to the end user.
Figure 4.23 shows a configuration using two individual LED’s – one for transmitted data the other for received data.

Figure 4.24 Single LED UART Configuration

In Figure 4.24 transmit and receive LED indicators are wire-OR’ed together to give a single LED indicator which indicates any transmit or receive data activity.

Note that the LED’s are connected to the same supply as VCCIO.

4.12 Send Immediate/Wake Up (SIWU#)

The SIWU# pin is available in the FIFO modes and in bit bang mode.

The Send Immediate portion is used to flush data from the chip back to the PC. This can be used to force short packets of data back to the PC without waiting for the latency timer to expire.

To avoid overrunning, this mechanism should only be used when a process of sending data to the chip has been stopped.

The data transfer is flagged to the USB host by the falling edge of the SIWU# signal. The USB host will schedule the data transfer on the next USB packet.

Figure 4.25 Using SIWU#

When the pin is being used for a Wake Up function to wake up a sleeping PC a 20ms negative pulse on this pin is required. When the pin is used to immediately flush the buffer (Send Immediate) a 250ns negative pulse on this pin is required.
Notes:

1. When using remote wake-up, ensure the resistors are pulled-up in suspend. Also ensure peripheral designs do not allow any current sink paths that may partially power the peripheral.
2. If remote wake-up is enabled, a peripheral is allowed to draw up to 2.5mA in suspend. If remote wake-up is disabled, the peripheral must draw no more than 500μA in suspend.
3. If a Pull-down is enabled, the FT232H will not wake up from suspend when using SIWU#.
4. In UART mode the RI# pin acts as the wake up pin.

4.13 FT232H Mode Selection

The FT232H defaults to asynchronous serial interface (UART) mode of operation.

After a reset the required mode is determined by the contents of the external EEPROM which can be programmed using `FT_Prog`.

The EEPROM contents determine if the FT232H device is configured as FT232 asynchronous serial interface, FT245 FIFO interface, CPU-style FIFO interface, FT1248 or Fast Serial Interface.

Following a reset, the EEPROM is read and the FT232H configured for the selected mode. After device enumeration, the `FT_SetBitMode` command (refer to `D2XX_Programmers_Guide`) can be sent to the USB driver to switch the selected interface into other modes – asynchronous bit-bang, synchronous bit-bang or MPSSE – if required.

When in FT245 FIFO mode, the `FT_SetBitMode` command can be used to select Synchronous FIFO (`FT_SetBitMode = 0x40`). Note that FT245 FIFO mode must be configured in the EEPROM before selecting the Synchronous FIFO mode.

The drive strength selection, slew rate and Schmitt input function can also be configured in the EEPROM.

The MPSSE can be configured directly using the D2XX commands. The `D2XX_Programmers_Guide` is available from the FTDI website. The application note `AN_108 – Command Processor for MPSSE and MCU Host Bus Emulation Modes` gives further explanation and examples for the MPSSE.

4.14 Modes Configuration

This section summarises what modes are configurable using the external EEPROM or the application software.

5 Devices Characteristics and Ratings

5.1 Absolute Maximum Ratings

The absolute maximum ratings for the FT232H devices are as follows. These are in accordance with the Absolute Maximum Rating System (IEC 60134). Exceeding these values may cause permanent damage to the device.

6 FT232H Configurations

The following section illustrates possible USB power configurations for the FT232H. All USB power configurations illustrated apply to both package options for the FT232H device.

6.1 USB Bus Powered Configuration

Bus Powered Application example 1: Bus powered configuration running on +5V.

Figure 6.1 illustrates the FT232H in a typical USB bus powered design configuration. A USB bus powered device gets its power from the VBUS (+5V) which is connected to VREGIN. In this application, the VREGIN is the +5V input to the on chip +3.3V/1.8V regulator. The output of the on chip LDO regulator (+1.8V) drives pin 38, (VCORE), and pin 37, (VCCA).

The output of the on chip LDO regulator (3.3V) supplies 3.3V to the VCCIOs, VPLL and VPHY through pin 39, VCCD. Please note that when the FT232H running on +5V (VREGIN), the VCCD becomes an output.

**Note:**

1. In this application, pin 40 (VREGIN) is the +5V input to the on chip +3.3V/1.8V regulator. Since the VREGIN is +5.0V, pin 39 (VCCD) becomes 3V3 output and supplies 3.3V to the VCCIOs, VPLL and VPHY.
2. The output of the on chip LDO +3.3V/1.8V regulator (+1.8V) drives pin 38, the FT232H core supply (VCORE) and pin 37, the VCCA.
6.2 USB Self Powered Configuration

6.2.1 Self-Powered Application Example 1

Self-powered configuration running on 5V.

Figure 6.2 Self-Powered Configuration Example 1

Figure 6.2 illustrates the FT232H in a typical USB self-powered configuration. A USB self-powered device gets its power from its own external power supply which is connected to VREGIN. In this application the VREGIN is the +5V input to the on chip +3.3V/1.8V regulator. The output of the on chip LDO regulator (+1.8V) drives pin 38, VCORE and pin 37, VCCA. The output of the on chip LDO regulator (3.3V) supplies 3.3V to the VCCIOs, VPLL and VPHY through VCCD.

Please note that when the FT232H running on +5V (VREGIN), the VCCD becomes an output.

Note that in this set-up, the EEPROM should be configured for self-powered operation and the option “suspend on ACBUS7 low” is enabled in FT_Prog. This configuration uses the ACBUS7 pin, when this function is enabled ACBUS7 should not be used as a GPIO in MPSSE mode.
6.2.2 Self-Powered Application Example 2

Self-powered configuration running on 3.3V.

Figure 6.3 Self-Powered Configuration Example 2

Figure 6.3 illustrates the FT232H in a typical USB self-powered configuration similar to Figure 6.2. The difference here is that the VREGIN is connected to the external 3V3 LDO regulator output which supplies 3.3V to the VCCIOs, VCCD, VPLL and VPHY. Please note that when the FT232H running on +3V3 (VREGIN), the VCCD becomes an input. In this application the VREGIN is the +3V3 input to the on chip+3.3V/1.8V regulator. The output of the on chip LDO regulator (+1.8V) drives pin 38, VCORE and pin 37, VCCA.

Note that in this set-up, the EEPROM should be configured for self-powered operation and the option "suspend on ACBUS7 low" selected in FT_Prog. This configuration uses the ACBUS7 pin, when this function is enabled ACBUS7 should not be used as a GPIO in MPSSE mode.
6.3 Oscillator Configuration

![Oscillator Configuration Diagram]

Figure 6.4 Recommended FT232H Oscillator Configuration

Figure 6.4 illustrates how to connect the FT232H with a 12MHz ± 0.003% crystal. In this case loading capacitors should be added between OSCI, OSCO and GND as shown. A value of 27pF is shown as the capacitor in the example – this will be good for many crystals but it is recommended to select the loading capacitor value based on the manufacturer’s recommendations wherever possible. It is recommended to use a fundamental mode, parallel cut type crystal.

It is also possible to use a 12 MHz Oscillator with the FT232H. In this case the output of the oscillator would drive OSCI, and OSCO should be left unconnected. The oscillator must have a CMOS output drive capability.

Table 6.1 OSCI Input characteristics
7 EEPROM Configuration

7.1 EEPROM Interface

The FT232H uses configuration data from an external EEPROM. The EEPROM must be 16 bits wide (93LC56B) and powered from the same net as the core supply of +2.97 to +3.63 volts. Adding an external (93LC56B) EEPROM allows the chip to be configured as a serial UART (RS232 mode), parallel FIFO (245) mode, FT1248, fast serial (opto isolation) or CPU-Style FIFO.

![FT232H pins](image-url)

**Figure 7.1 EEPROM Interface**

The external EEPROM can also be used to customise the USB VID, PID, Serial Number, Product Description Strings and Power Descriptor value of the FT232H for OEM applications. Other parameters controlled by the EEPROM include Remote Wake Up, Soft Pull Down on Power-Off and I/O pin drive strength.

If the FT232H is used without an external EEPROM the chip defaults to a USB to asynchronous serial UART (RS232 mode) port device. If no EEPROM is connected (or the EEPROM is blank), the FT232H uses its built-in default VID (0403h), PID (6014h) Product Description and Power Descriptor Value. In this case, the device will not have a serial number as part of the USB descriptor.

7.2 Default EEPROM Configuration

The external EEPROM (if it’s fitted) can be programmed over USB using FT_Prog. This allows a blank part to be soldered onto the PCB and programmed as part of the manufacturing and test process. Users who do not have their own USB Vendor ID but who would like to use a unique Product ID in their design can apply to FTDI for a free block of unique PIDs.

Contact FTDI support for this service.

8 Package Parameters

The FT232H is available in two different packages. The FT232HL is the LQFP-48 option and the FT232HQ is the QFN-48 package option. The solder reflow profile for both packages is described in section 8.3.

8.1 FT232HQ, QFN-48 Package Dimensions

**Figure 8.1 48 pin QFN Package Details**

**Notes:**
1. All dimensions are in mm.
2. The date code format is **YYXX** where XX = 2 digit week number, YY = 2 digit year number. This is followed by the revision number.
3. The code **XXXXXXX** is the manufacturing LOT code.
4. The central soldering pad is floating. Connect it to GND.
8.2 FT232HL, LQFP-48 Package Dimensions

Figure 8.2 48 pin LQFP Package Details

Notes:
1. All dimensions are in mm.
2. The date code format is YYXX where XX = 2 digit week number, YY = 2 digit year number. This is followed by the revision number.
3. The code XXXXXXXX is the manufacturing LOT code.

Distributor and Sales Representatives

Please visit the Sales Network page of the FTDI Web site for the contact details of our distributor(s) and sales representative(s) in your country.

System and equipment manufacturers and designers are responsible to ensure that their systems, and any Future Technology Devices International Ltd (FTDI) devices incorporated in their systems, meet all applicable safety, regulatory and system-level performance requirements. All application-related information in this document (including application descriptions, suggested FTDI devices and other materials) is provided for reference only. While FTDI has taken care to assure it is accurate, this information is subject to customer confirmation, and FTDI disclaims all liability for system designs and for any applications assistance provided by FTDI. Use of FTDI devices in life support and/or safety applications is entirely at the user's risk, and the user agrees to defend, indemnify and hold harmless FTDI from any and all damages, claims, suits or expense resulting from such use. This document is subject to change without notice. No freedom to use patents or other intellectual property rights is implied by the publication of this document. Neither the whole nor any part of the information contained in, or the product described in this document, may be adapted or reproduced in any material or electronic form without the prior written consent of the copyright holder. Future Technology Devices International Ltd, Unit 1, 2 Seaward Place, Centurion Business Park, Glasgow G41 1HH, United Kingdom. Scotland Registered Company Number: SC136640.

### Appendix C – Revision History

<table>
<thead>
<tr>
<th>Revision</th>
<th>Changes</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version 1.0</td>
<td>Initial Release</td>
<td>2011-02-24</td>
</tr>
<tr>
<td>Version 1.1</td>
<td>Changes made to ACBUS7 details; Updated the reset line of the schematics; Added USB Compliance logo and TID</td>
<td>2011-04-19</td>
</tr>
<tr>
<td>Version 1.2</td>
<td>Corrected TID Number</td>
<td>2011-04-29</td>
</tr>
<tr>
<td>Version 1.3</td>
<td>Changed the value of recommended capacitor on the Reset# pin; Changed signal label of WR to WR#</td>
<td>2011-05-16</td>
</tr>
<tr>
<td>Version 1.4</td>
<td>Missing #(active low) on WR signal page 8 and page 40; Enhanced recommended schematics.</td>
<td>2011-09-08</td>
</tr>
<tr>
<td>Version 1.5</td>
<td>Added Pin 31 ACBUS7 Description (Table 0.1); Added Package Dimension Tolerance in Section 8.2; Added a list of unsupported baud rates to section 4.1 data transfer rate</td>
<td>2011-11-25</td>
</tr>
<tr>
<td>Version 1.6</td>
<td>Updated section 1.1, Linux Version; Updated Timing information, Figure 4.21 and Table 4.8; Updated section 7.2 default descriptors</td>
<td>2012-01-25</td>
</tr>
<tr>
<td>Version 1.7</td>
<td>Added a note on Section 4.2, EEPROM interface; 93LC46B is not compatible with the FT232H</td>
<td>2012-06-21</td>
</tr>
<tr>
<td>Version 1.8</td>
<td>Modified the IC mark, Figure 8.1 and Figure 8.2; Update contact information</td>
<td>2012-12-13</td>
</tr>
<tr>
<td>Version 1.81</td>
<td>Added detail to QFN drawing regarding the center pad; Corrected figure 6.4; Added clarification for which signals are 5V tolerant; Clarified ACBUS default functions on P8</td>
<td>2013-01-04</td>
</tr>
<tr>
<td>Version 1.82</td>
<td>Updated ADBUS7 to ACBUS7 on page 10; Added support for Windows 10; Removed year from the copyright information</td>
<td>2016-02-05</td>
</tr>
<tr>
<td>Version 1.83</td>
<td>Corrected the typo error in table 3.13</td>
<td>2017-11-22</td>
</tr>
<tr>
<td>Version 1.84</td>
<td>Updated Section 6.2.2 (Self-Powered Application Example 2- ACBUS7 pin function)</td>
<td>2018-05-11</td>
</tr>
</tbody>
</table>
